5.137 elem

	DESCRIPTION	LINKS	GRAPH	AUTOMATON
Origin	Derived from element.			
Constraint	$\mathtt{elem}(\mathtt{ITEM},\mathtt{TABLE})$			
Usual name	element			
Synonyms	nth, array.			
Arguments	<pre>ITEM : collection(index-d TABLE : collection(index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-index-inde</pre>			
Restrictions	$\begin{array}{l} \textbf{required}(\texttt{ITEM}, [\texttt{index}, \texttt{value}]) \\ \textbf{ITEM}. \texttt{index} \geq 1 \\ \textbf{ITEM}. \texttt{index} \leq \texttt{TABLE} \\ \texttt{ITEM} = 1 \\ \texttt{TABLE} > 0 \\ \textbf{required}(\texttt{TABLE}, [\texttt{index}, \texttt{value}]) \\ \textbf{TABLE}. \texttt{index} \geq 1 \\ \textbf{TABLE}. \texttt{index} \leq \texttt{TABLE} \\ \textbf{distinct}(\texttt{TABLE}, \texttt{index}) \end{array}$			

Purpose

ITEM is equal to one of the entries of the table TABLE.

Example

```
\left(\begin{array}{c} \langle \mathtt{index} - 3 \ \mathtt{value} - 2 \rangle\,, \\ \mathtt{index} - 1 \quad \mathtt{value} - 6, \\ \langle \mathtt{index} - 2 \quad \mathtt{value} - 9, \\ \mathtt{index} - 3 \quad \mathtt{value} - 2, \\ \mathtt{index} - 4 \quad \mathtt{value} - 9 \end{array}\right)
```

The elem constraint holds since its first argument ITEM corresponds to the third item of the TABLE collection.

Typical

```
|{\tt TABLE}| > 1 \\ {\tt range}({\tt TABLE.value}) > 1
```

Symmetries

- Items of TABLE are permutable.
- All occurrences of two distinct values in ITEM.value or TABLE.value can be swapped; all occurrences of a value in ITEM.value or TABLE.value can be renamed to any unused value.

Arg. properties

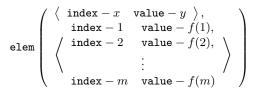

Functional dependency: ITEM.value determined by ITEM.index and TABLE.

Usage

Makes the link between the discrete decision variable INDEX and the variable VALUE according to a given table of values TABLE. We now give five typical uses of the elem constraint.

1. In some problems we may have to represent a function y=f(x) (with $x\in[1,m]$). In this context we generate the following elem constraint where INDEX is a domain variable taking its values in $\{1,2,\ldots,m\}$:

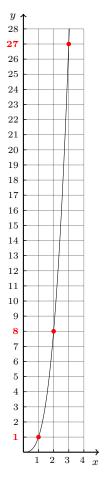

Figure 5.311: $y = x^3 \ (1 \le x \le 3)$

As an example, consider the problem of finding the smallest integer that can be de-

composed in two different ways in the sum of two cubes [202]. The elem constraint can be used for representing the function $y = x^3$ (Figure 5.311). The unique solution $1729 = 12^3 + 1^3 = 10^3 + 9^3$ can be obtained by the following set of constraints:

```
elem(\langle index - x_1 value - y_1 \rangle,
              \langle \mathtt{index} - 1 \ \mathtt{value} - 1, \mathtt{index} - 2 \ \mathtt{value} - 8, \dots, \mathtt{index} - 20 \ \mathtt{value} - 8000 \rangle)
    elem(\langle index - x_2 value - y_2 \rangle,
              \langle \mathtt{index} - 1 \mathtt{ value} - 1, \mathtt{index} - 2 \mathtt{ value} - 8, \ldots, \mathtt{index} - 20 \mathtt{ value} - 8000 \rangle \rangle
    elem(\langle index - x_3 value - y_3 \rangle,
              \langle \mathtt{index} - 1 \mathtt{ value} - 1, \mathtt{index} - 2 \mathtt{ value} - 8, \ldots, \mathtt{index} - 20 \mathtt{ value} - 8000 \rangle)
    elem(\langle index - x_4 value - y_4 \rangle,
              \langle \mathtt{index} - 1 \mathtt{ value} - 1, \mathtt{index} - 2 \mathtt{ value} - 8, \dots, \mathtt{index} - 20 \mathtt{ value} - 8000 \rangle)
   y_1 + y_2 = y_3 + y_4
   x_1 < x_2
   x_3 < x_4
x_1 < x_3
```

The last three inequalities constraints in the conjunction are used for breaking symmetries. The constraints $x_1 < x_2$ and $x_3 < x_4$ respectively order the pairs of variables (x_1, x_2) and (x_3, x_4) from which the sums $x_1^3 + x_2^3$ and $x_3^3 + x_4^3$ are generated. Finally the inequality $x_1 < x_3$ enforces a lexicographic ordering between the two pairs of variables (x_1, x_2) and (x_3, x_4) .

2. In some optimisation problems a classical use of the elem constraint consists expressing the link between a discrete choice and its corresponding cost. For each discrete choice we create an elem constraint of the form:

where:

- Choice is a domain variable that indicates which alternative will be finally selected.
- Cost is a domain variable that corresponds to the cost of the decision associated with the value of the Choice variable,
- $Cost_1, Cost_2, \ldots, Cost_m$ are the respective costs associated with the alternatives $1, 2, \ldots, m$.
- 3. In some problems we need to express a disjunction of the form $VAR = VAR_1 \vee VAR =$ $\mathtt{VAR}_2 \lor \cdots \lor \mathtt{VAR} = \mathtt{VAR}_n.$ This can be directly reformulated as the following elem constraint, where INDEX is a domain variable taking its value in the finite set $\{1, 2, \dots, n\}$ and where the TABLE argument corresponds to the domain variables $VAR_1, VAR_2, \ldots, VAR_n$:

20030820 1129

4. In some scheduling problems the duration of a task depends on the machine where the task will be assigned in final schedule. In this case we generate for each task an elem constraint of the following form:

$$\left(egin{array}{ccccc} \left(& {
m index-Machine} & {
m value-Duration} \
ight), \\ & {
m index-1} & {
m value-Dur_1}, \\ \left\langle & {
m index-2} & {
m value-Dur_2}, \
ight. \\ & {
m index-}m & {
m value-Dur}_m \end{array}
ight)$$

where:

- Machine is a domain variable that indicates the resource to which the task will be assigned,
- Duration is a domain variable that corresponds to the duration of the task,
- Dur₁, Dur₂,..., Dur_m are the respective duration of the task according to the hypothesis that it runs on machine 1, 2 or m.

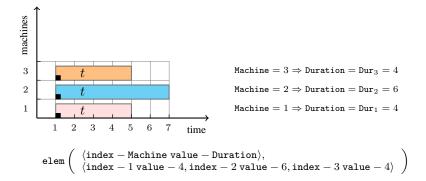

Figure 5.312: A task t for which the duration depends on the machine 1, 2 or 3 to which it is assigned

Figure 5.312 illustrates this particular use of the elem constraint for modelling that a task has a duration of 4, 6 and 4 when we respectively assign it on machines 1, 2 and 3.

5. In some vehicle routing problems we typically use the elem constraint to express the distance between location i and the next location visited by a vehicle. For this purpose we generate for each location i an elem constraint of the form:

$$egin{aligned} \left(egin{array}{cccc} \operatorname{index} - \operatorname{Next}_i & \operatorname{value} - \operatorname{distance}_i \end{array}
ight), \ \operatorname{index} - 1 & \operatorname{value} - \operatorname{Dist}_{i_1}, \ \left\langle & \operatorname{index} - 2 & \operatorname{value} - \operatorname{Dist}_{i_2}, \ & dots \ & \vdots \ & \operatorname{index} - m & \operatorname{value} - \operatorname{Dist}_{i_m} \end{array}
ight) \end{aligned}$$

where:

Next_i is a domain variable that gives the index of the location the vehicle will
visit just after location i,

- distance_i is a domain variable that corresponds to the distance between location i and the location the vehicle will visit just after,
- ullet Dist i_1 , Dist i_2 , ..., Dist i_m are the respective distances between location i and locations $1,2,\ldots,m$.

An other example where the table argument corresponds to domain variables is described in the keyword entry assignment to the same set of values.

Remark

Originally, the parameters of the elem constraint had the form element(INDEX, TABLE, VALUE), where INDEX and VALUE were two domain variables and TABLE was a list of non-negative integers.

Within some systems (e.g., Gecode), the index of the first entry of the table TABLE corresponds to 0 rather than to 1.

When the first entry of the table TABLE corresponds to a value p that is different from 1 we can still use the elem constraint. We use the reformulation $I=J-p+1 \land {\tt elem}(\langle {\tt index}-I {\tt value}-V \rangle, {\tt TABLE}),$ where I and J are domain variables respectively ranging from 1 to $|{\tt TABLE}|$ and from p to $p+|{\tt TABLE}|-1$.

Graph property(ies)

NARC= 1

Graph model

We regroup the INDEX and VALUE parameters of the original element constraint element(INDEX, TABLE, VALUE) into the parameter ITEM. We also make explicit the different indices of the table TABLE.

Parts (A) and (B) of Figure 5.313 respectively show the initial and final graph associated with the **Example** slot. Since we use the **NARC** graph property, the unique arc of the final graph is stressed in bold.

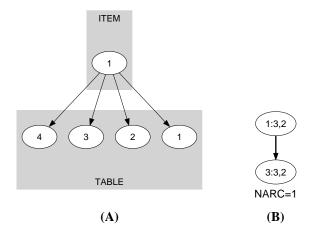

Figure 5.313: Initial and final graph of the elem constraint

Signature

Since all the index attributes of TABLE are distinct and because of the first condition of the arc constraint the final graph cannot have more than one arc. Therefore we can rewrite $\mathbf{NARC} = 1$ to $\mathbf{NARC} \geq 1$ and simplify $\overline{\mathbf{NARC}}$ to $\overline{\mathbf{NARC}}$.

Automaton

Figure 5.314 depicts the automaton associated with the elem constraint. Let INDEX and VALUE respectively be the index and the value attributes of the unique item of the ITEM collection. Let INDEX_i and VALUE_i respectively be the index and the value attributes of item i of the TABLE collection. To each quadruple (INDEX, VALUE, INDEX_i, VALUE_i) corresponds a 0-1 signature variable S_i as well as the following signature constraint: $((INDEX = INDEX_i) \land (VALUE = VALUE_i)) \Leftrightarrow S_i$.

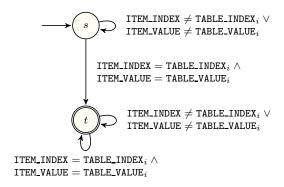

Figure 5.314: Automaton of the elem(ITEM, TABLE) constraint (once one finds the right item – index and value – in the table, one switches from the initial state s to the accepting state t)
