5.126 disjunctive

DESCRIPTION LINKS GRAPH Origin [91] Constraint disjunctive(TASKS) Synonym one_machine. TASKS : collection(origin-dvar, duration-dvar) Argument Restrictions required(TASKS,[origin,duration]) ${\tt TASKS.duration} \geq 0$ All the tasks of the collection TASKS that have a duration strictly greater than 0 should **Purpose** not overlap. $\mathtt{origin}-1$ duration - 3, origin - 2duration - 0, **Example** ${\tt origin}-7$ duration - 2, ${\tt duration}-1$

Figure 5.298 shows the tasks with non-zero duration of the example. Since these tasks do not overlap the disjunctive constraint holds.

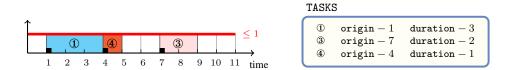

Figure 5.298: Tasks with non-zero duration of the Example slot

All solutions

Figure 5.299 gives all solutions to the following non ground instance of the disjunctive constraint: $O_1 \in [2,5]$, $D_1 \in [2,4]$, $O_2 \in [2,4]$, $D_2 \in [1,6]$, $O_3 \in [3,6]$, $O_3 \in [4,4]$, $O_4 \in [2,7]$, $O_4 \in [1,3]$, disjunctive($\langle O_1 D_1, O_2 D_2, O_3 D_3, O_4 D_4 \rangle$).

Typical

 $\begin{aligned} |{\tt TASKS}| &> 2 \\ {\tt TASKS.duration} &\geq 1 \end{aligned}$

Symmetries

- Items of TASKS are permutable.
- TASKS.duration can be decreased to any value ≥ 0 .
- One and the same constant can be added to the origin attribute of all items of TASKS.

Arg. properties

Contractible wrt. TASKS.

Usage

The disjunctive constraint occurs in many resource scheduling problems in order to model a resource that can not be shared. This means that tasks using this resource can not overlap in time. Quite often disjunctive constraints are used together with precedence constraints. A precedence constraint between two tasks models the fact that the processing of a task has to be postponed until an other task is completed. Such mix of disjunctive and precedence constraints occurs for instance in job-shop problems.

Remark

Some systems like Ilog CP Optimizer also imposes that zero duration tasks do not overlap non-zero duration tasks.

A soft version of this constraint, under the hypothesis that all durations are fixed, was presented by P. Baptiste *et al.* in [18]. In this context the goal was to perform as many tasks as possible within their respective due-dates.

When all tasks have the same (fixed) duration the disjunctive constraint can be reformulated as an all_min_dist constraint for which a filtering algorithm achieving bound-consistency is available [11].

Within the context of linear programming [215, page 386] provides several relaxations of the disjunctive constraint.

Some solvers use in a pre-processing phase, while stating precedence and cumulative constraints, an algorithm for automatically extracting large cliques [88] from a set of tasks that should not pairwise overlap (i.e., two tasks t_i and t_j can not overlap either, because t_i ends before the start of t_j , either because the sum of resource consumption of t_i and t_j exceeds the capacity of a cumulative resource that both tasks use) in order to state disjunctive constraints.

Algorithm

We have four main families of methods for handling the disjunctive constraint:

 Methods based on the compulsory part [250] of the tasks (also called time-tabling methods). These methods determine the time slots which for sure are occupied by a given task, an propagate back this information to the attributes of each task (i.e., the origin and the duration). Because of their simplicity, these methods have been originally used for handling the disjunctive constraint. Even if they propagate less than the other methods they can in practice handle a large number of tasks. To our best knowledge no efficient incremental algorithm devoted to this problem was published up to now (i.e., September 2006).

- Methods based on constructive disjunction. The idea is to try out each alternative of
 a disjunction (e.g., given two tasks t₁ and t₂ that should not overlap, we successively
 assume that t₁ finishes before t₂, and that t₂ finishes before t₁) and to remove values
 that were pruned in both alternatives.
- Methods based on *edge-finding*. Given a set of tasks T, edge-finding determines that some task must, can, or cannot execute first or last in T. Efficient edge-finding algorithms for handling the disjunctive constraint were originally described in [92, 93] and more recently in [432, 304].
- Methods that, for any task t, consider the maximal number of tasks that can end up before the start of task t as well as the maximal number of tasks that can start after the end of task t [442].

All these methods are usually used for adjusting the minimum and maximum values of the variables of the disjunctive constraint. However some systems use these methods for pruning the full domain of the variables. Finally, *Jackson priority rule* [225] provides a necessary condition [93] for the disjunctive constraint. Given a set of tasks \mathcal{T} , it consists to progressively schedule all tasks of \mathcal{T} in the following way:

- It assigns to the first possible time point (i.e., the earliest start of all tasks of \mathcal{T}) the available task with minimal latest end. In this context, available means a task for which the earliest start is less than or equal to the considered time point.
- It continues by considering the next time point until all the tasks are completely scheduled.

Systems

disjunctive in Choco, unary in Gecode.

See also

common keyword: calendar, disj, disjunctive_or_same_end,
disjunctive_or_same_start(scheduling constraint).

generalisation: cumulative (task heights and resource limit are not necessarly all equal to 1), diffn(task of height 1 replaced by orthotope).

implied by: precedence.

implies: disjunctive_or_same_end, disjunctive_or_same_start.

specialisation: all_min_dist(line segment replaced by line segment, of same length), alldifferent(task replaced by variable).

Keywords

characteristic of a constraint: core, sort based reformulation.

complexity: sequencing with release times and deadlines.

constraint type: scheduling constraint, resource constraint, decomposition.

filtering: compulsory part, constructive disjunction, Phi-tree.

modelling: disjunction, sequence dependent set-up, zero-duration task.

modelling exercises: sequence dependent set-up.

problems: maximum clique.

```

Graph model

We generate a *clique* with a non-overlapping constraint between each pair of distinct tasks and state that the number of arcs of the final graph should be equal to the number of arcs of the initial graph.

Parts (A) and (B) of Figure 5.300 respectively show the initial and final graph associated with the **Example** slot. The disjunctive constraint holds since all the arcs of the initial graph belong to the final graph: all the non-overlapping constraints holds.

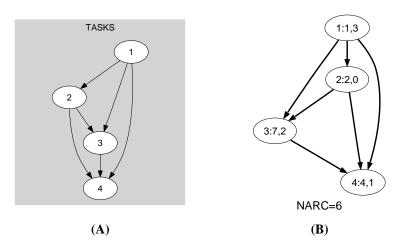

Figure 5.300: Initial and final graph of the disjunctive constraint

Quiz

EXERCISE 1 (checking whether a ground instance holds or not)

- **A.** Does the constraint disjunctive($\langle\langle 2 2 \rangle, \langle 4 5 \rangle, \langle 8 2 \rangle\rangle$) hold?
- **B.** Does the constraint disjunctive($\langle\langle 1 3 \rangle, \langle 4 4 \rangle, \langle 8 2 \rangle\rangle$) hold?
- C. Does the constraint disjunctive((\langle 3 2 \rangle, \langle 4 0 \rangle, \langle 7 3 \rangle \rangle) hold?

^aHint: go back to the definition of disjunctive.

20050506 1095

SOLUTION TO EXERCISE 1

- **A.** No, since tasks 2 and 3 overlap at instant 8.
- **B.** Yes, since the three tasks do not overlap:
 - Tasks ① and ② do not overlap since task ① ends before task ②,
 - Tasks ① and ③ do not overlap since task ① ends before task ③,
 - Tasks 2 and 3 do not overlap since task 2 ends before task 3.
- C. Yes, since tasks ① and ③ do not overlap and since the duration of task ② is zero.
